KOREA COUPLING CO., LTD

Korea Coupling Co., Ltd is specialized and global market leader of power transmission components manufacturer from Korea since 1992.

We have been supplying high quality and valued products to various industries such as coal mining, paper, food industries, and petro chemical, steel, and cement mills.

Korea Coupling's products are mainly used for hydraulic machineries, pumps, blower fans, conveyors, and cranes as well as general power driven industrial equipments.

The management philosophy of Korea Coupling is creating and serving the best engineered power transmission products in the duration to our valued clients and new global and domestic market with supporting a higher standard of performance.

We consistently do our utmost to produce and improve the best value of our products and services. Your deserved patronage and great relationships along with closer contacts will be greatly appreciated.

Wishing you everlasting prosperity and significant cooperation.

Coupling Selection

How to Select

Standard Selection

The Standard Selection may be used for engine driven, motor, or turbine applications. The following information is required:

- Application or equipment type (motor to pump, reducer to conveyor, etc.)
- Shaft diameters (mm)
- Gaps between shafts (mm)
- Speed (RPM)
- Horsepower or torque (Nm)

1. Rating : Determine system torque. Torque is calculated as follows :

$$\text{I . Torque (Nm)} = \frac{\text{kW} \times 9,550}{\text{RPM}} \quad \text{II . Torque (Kg.m)} = \frac{\text{kW} \times 974}{\text{RPM}}$$

2. Service Factor : Determine appropriate service factor from page. 5-6

3. Minimum Coupling Rating : Determine the required minimum coupling rating as follows :

$$\text{Minimum Coupling Rating} = \text{Service Factor} \times \text{Torque (Nm)}$$

4. Type : Select the appropriate coupling type

5. Size : Trace the Torque column to find the value that is equal or greater than value from Step 3.

6. Check : Check speed (RPM), bore, gap and dimensions.

Formula Selection

The Standard Selection should be used for most coupling selections.

The Formula Selection procedure below should be used for:

- High Peak Loads.
- Brake Applications (Brake disc or brake wheel is an integral part of coupling)

Using the Formula Selection and providing system peak torque and frequency, duty cycle, and brake torque rating will allow for a more refined selection.

1. High Peak Loads : Use formula A or B for applications which involve motors with higher than normal torque characteristics. Applications should also be those with intermittent operations, including shock loading, inertia effects due to starting and stopping, system-induced repetitive high peak torques. System Peak Torque is the maximum torque that can exist in the system. Select a coupling with a Torque Rating equal or greater than the Selection Torque calculated below:

A. Non-Reversing High Peak Torque : Selection torque (Nm) = System Peak Torque or

$$\text{System Torque (Nm)} = \frac{\text{System peak kW} \times 9549}{\text{RPM}}$$

B. Reversing High Peak Torque : Selection Torque (Nm) = 2 x System Peak Torque or

$$\text{System Torque (Nm)} = \frac{2 \times \text{Peak kW} \times 9549}{\text{RPM}}$$

2. Brake Applications : If the torque rating of the brake exceeds the motor torque, use brake rating as blow :

$$\text{Selection Torque (Nm)} = \text{Brake Torque Rating} \times \text{Service Factor}$$

Service Factors

Service Factors for Operation of Drive System

Application	Service Factor
AERATOR	2.0
AGITATORS	
Vertical and Horizontal Scenv, Propeller, Paddle	1.0
BARGE HAUL PULLER	1.5
BLOWERS

Spinner, Tenter Frame, Winder	1.5

Service Factors

Standard Selection

Service Factors for engine drives are required for applications where good flywheel regulation prevents torque fluctuations greater than $\pm 20\%$. For drives where torque fluctuations are greater or where the operation is near a serious critical or torsional vibration, a mass elastic study is necessary.

Number of Cylinders	4 or 5					6 or more				
Service Factor	1.5	1.75	2	2.25	2.5	1.5	1.75	2	2.25	2.5
Engine Service Factor	2.5	2.75	3	3.25	3.5	2.5	2.75	3	3.25	3.5

To use Engine Drive Service Factors, first determine application Service Factor from page 5-6. When Service Factor is greater than 2.0, or where 1, 2 or 3 cylinder engines are involved, refer complete application details to Korea Coupling for engineering review.

Service Factors are a guide, based on experience, of the ratio between coupling catalogue rating and system characteristics. The system characteristics are best measured with a torque meter.

Torque Demands Driven Machine	Typical applications for Driven Equipment	Typical Service Factor
	Constant torque such as Centrifugal Pumps, Blowers and Compressors.	1.0
	Continuous duty with some torque variations including Plastic Extruders, Forced Draft Fans.	1.5
	Light shock loads from Metal Extruders, Cooling Towers, Cane Knife, Log Haul.	2.0
	Moderate shock loading as expected from a Car Dumper, Stone Crusher, Vibrating Screen.	2.5
	Heavy shock load with some negative torques from Roughing Mills, Reciprocating Pumps, Compressors, Reversing Runout Talbes.	3.0
	Applications like Reciprocating Compressors with frequent torque reversals, which do not necessarily cause reverse rotations.	Refer to KCP

Taper Grid Couplings

Horizontal Split Cover Type

- Best Choice for limited spaces
- Allows easy access to the grid spring
- Suitable for reversing applications
- Light weight, die-cast aluminum grid cover

Vertical Split Cover Type

- Best choice for high operating speeds
- Allows easy access to the grid spring
- Steel grid cover for strength

KCP Tapered Grid Couplings are shaft-to-shaft couplings that are of compact size, yet can handle torque capacity due to their high strength hardened alloy steel construction.

The tapered grids are designed with a trapezoidal cross section and are tempered for spring hardness. Through a high-precision operation called shot peening, the surface molecules are compressed by high-velocity steel micro beads. The compression of the molecules results in dramatic increase in strength rating and provides reserve strength for a longer part life.

The tapered grids are accessible through the unit's removable cover. It is extremely easy to fit the trapezoidal grids into the slots of the hub, compared to fitting rectangular grids. There is no need for the equipment to be moved (hence downtime) so that couplings can be installed.

Due to their compact size, the tapered grids can simply be placed directly in the slots of the hub. Finally, the practical split cover can be placed using standard tools.

Protection Against Shaft Misalignment

The tapered grids are free to rock, pivot, and float within the hub teeth. This provides generous capacity for misalignment without producing the detrimental side loads on the bearings that are often created when couplings are misaligned.

Protection Against Shock & Vibratory loads

KCP Tapered Grid Couplings are able to deflect torsionally when subjected to normal shock or vibratory loads, so they are able to handle changing load conditions.

The system truly is a shock absorber for rotary motion, relying on the predictable resilience of the grid for torsional flexibility. The tapered grids "tune" the drive system. Due to their spring hardness, the grids absorb impact by spreading the impact energy over time. The grids can also damp vibration and reduce the peak or shock loads experienced by the rest of the system.

Taper Grid Coupling Types

T10 Type

T10 Type (Large)

T20 Type

T31 Type (Full Spacer)

T35 Type (Half Spacer)

T50 Type (Spacer)

T63 Type

KBW Type

T10 & G82 Type (Floating Shaft)

Vibration & Shock

Light Load

The grid contacts near the outer edges of the hub teeth. A long span between the points of contact remains free to flex under load.

Normal Load

As the load increases, the distance between the contact points on the hub teeth is shortened, but a free span still remains to cushion the load.

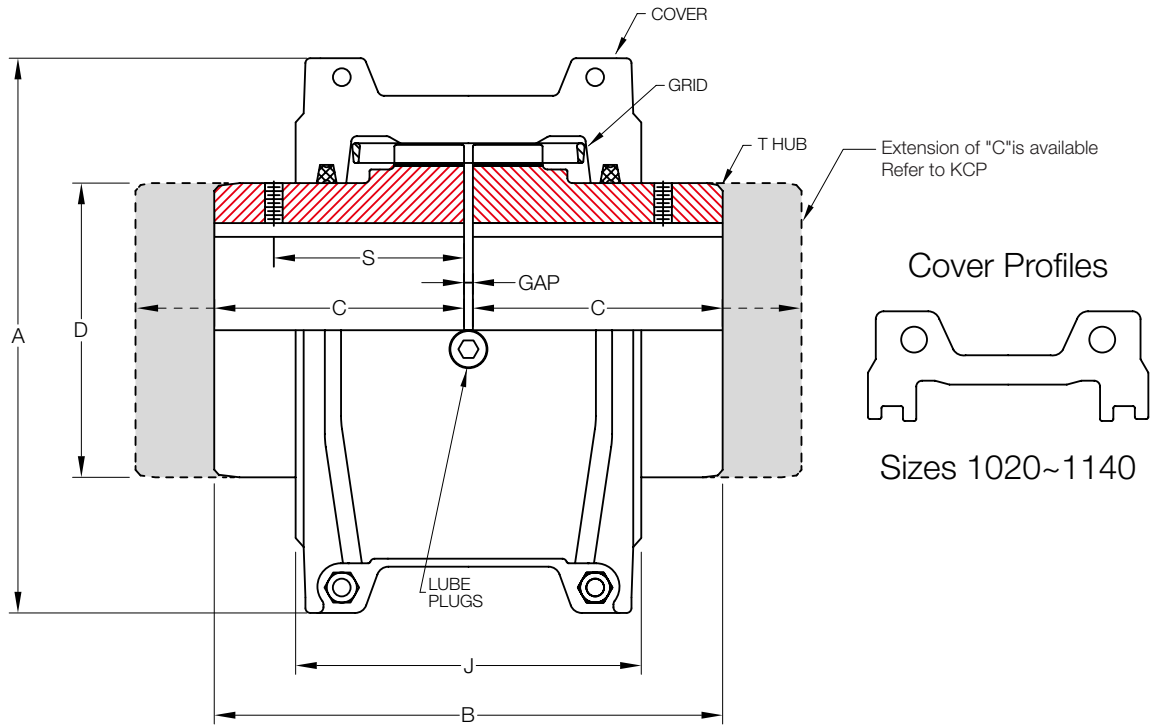

Shock Load

The coupling is flexible within its rated capacity. Under extreme overloads, the grid bears fully on the hub teeth and transmits full load directly.

Taper Grid Couplings

Installation

Requirements are wrenches, a straight edge and feeler gauges to install KCP Taper Grid Couplings. Taper Grid Coupling size from 1020 to 1090 are furnished for a clearance fit with a setscrew over the keyway. Larger sizes (from 1100 and up) are furnished for an interference fit without a setscrew.

Clearance fit Hubs : Clean all parts using a non-flammable solvent. Check hubs, shafts and key ways for burrs. Install keys. Mount hubs with the flange face flush with shaft ends (or as otherwise specified). Tighten setscrews. Do not heat clearance fit hubs.

Interference Fit Hubs : Furnished without setscrews.

1) Mount Seals and Hubs

Lock out starting switch of prime mover. Clean metal parts using a non-flammable solvent. Lightly coat seals with grease and place on shafts before mounting hubs. Heat interference fit hubs. Seal keyways to prevent leakage. Mount hubs on their corresponding shafts so that the hub face is flush with the end of the shaft (unless otherwise indicated).

2) Gap and Alignment

Use a spacer bar equal in thickness to the gap between shafts (Page 11-12) Insert bar and same depth at 90° intervals and measure clearance between bar and hub face with feelers. The difference in minimum and maximum measurements must not exceed the angular installation limits.

3) Offset Alignment

Align a straight edge so that it rests squarely on both hubs as shown in the diagram. Check with feelers. The clearance must not exceed the parallel offset installation limits. Tighten all foundation bolts and repeat Steps 2 and 3. Realign coupling if necessary.

4) Insert Grid

Pack the gap and grooves with specified lubricant before inserting grid. When grids are furnished in two or more segments, install them so that all cut ends extend in the same direction. This will assure correct contact between the grid and any non-rotating pins in each half of the covers. Spread the grid just enough so that it passes over the coupling teeth. Seat with a soft mallet.

Installation

5) Pack

Pack any spaces between and around the grid with as much lubricant as possible. Wipe off any excess so that any remaining lubricant is flush with top of grid. Position hub seals to line up with the grooves in the cover. Position gaskets on lower cover half flange and assemble the two covers so that the match marks are on the same side. If shafts are not horizontally level, or if the coupling is to be used vertically, assemble cover halves with the lug so that the match marks are up or are on the high side. Push gaskets in against the seals as far as possible. Secure cover halves with fasteners and tighten to torque. Make sure gaskets stay in position while the fasteners are tightened.

Annual Maintenance

Items to perform annually :

1. Check alignment. If the maximum operating misalignment limits are exceeded, realign the coupling to the recommended installation limits.
2. Check that all fasteners are tightened to torque.
3. Inspect Oil Seal and Gasket to determine if replacement is required. Replace if the Seal and Gasket is leaking grease.
4. Disassemble the coupling and inspect for wear. Replace any worn parts. Clean grease from coupling and repack with new grease. Install coupling using a new gasket as instructed in this manual.

Taper Grid Couplings

Alignment Data

Accurate alignment results in the maximum life and minimum maintenance for the coupling and the connected machinery. The amount of time for a coupling to reach its maximum operating limits is a function of load, operating speed, and lubrication. Maximum operating values listed in the table below are based on the allowable RPM listed on the catalogue. Values listed are based on the use of the specified gaps, use of standard coupling components, standard assemblies, and catalogue allowable speeds. Values may be combined for an installation or operating condition. Parallel misalignment is the distance between the centers of each shaft. Angular misalignment is dimension X minus dimension Y as shown in the drawing below. End float is the axial movement of the hubs within the covers as measured from "0" gap. This measure assumes zero angular and zero parallel misalignment.

Parallel Misalignment

Angular Misalignment

End Float

Misalignment Capacity

Gear Couplings

KCP Gear Couplings serve as a mechanical device which connect the shafts of two distinct machines and can accommodate large axial moments as well as small amounts of shaft misalignment.

Commercial Gear Couplings transmit more torque than other types of couplings of similar physical size. Because of this superior load transmitting capability, Gear Couplings have become widely used for higher speed applications, as well as for applications that require a combination of high torque capacity and a low inertia of the drive system.

Gear Couplings are torsionally rigid and couple two designs, one of which is completely flexible and one of which is rigid. Gear Couplings consist of two shaft hubs with external teeth, which are then connected by means of a sleeve, usually two pieces, containing internal teeth. A flexible spline with the hubs and sleeves rotating together is the working action of a Gear Coupling. The proper type of lubrication, applied frequently and adequately, is essential for the successful operation of this system.

This coupling is made up of one flexible geared half and on rigid half. A flexible & rigid coupling such as this is primarily used for "floating shaft" applications. The coupling accommodates angular misalignment but does not accommodate parallel displacement of shafts.

Gear Couplings

Installation

KCP Gear Couplings are designed to provide a mechanical connection between the rotating shafts of mechanical equipment, using gear mesh accommodate inherent misalignment while transmitting the power and torque between the connected shaft.

1) Mount Flanged Sleeves, Seals and Hub

- Examine the coupling assembly to insure there is no visible damage.
- Clean the hub bores and shafts using lint free cloth. Remove any nicks or burrs.
- When assembled, the keys should have a close side to side fit in the keyways in the hub and shaft with a slight clearance over the top of the keys.
- Place the flanged sleeves with oil rings on shafts before mounting flex hubs.

2) Straight Bore with Clearance / Slip Fit

- Install the keys in the shaft.
- Check to be sure that the set screws in the hub do not protrude into the keyway or the bore. Remove or back out the set screw to provide clearance during assembly.
- Slide the hub up the shaft to the desired axial position.
- Assemble and tighten the set screws using a calibrated torque wrench.

3) Straight Bore with interference Fit

- Accurately measure the bore and shaft diameters to assure proper fit.
- Install the keys in the shaft.
- heat the hub (135°C) in an oven until the bore is efficiently larger than the shaft.
- When the hub expanded, install it on the shaft to the desired axial position.

4) Taper Bore

- Check for acceptable contact pattern between the hub and the shaft.
- Put the hub on the shaft, keeping the keyways aligned.
- Lightly tap the face of the hub with a soft mallet. The resultant position will provide a starting point for the hub axial draw up.
- Use a depth micrometer to measure the distance from the shaft end to the hub face, and record the dimension.
- Mount a dial indicator to read axial hub advancement. Alternatively, the indicator can be positioned to contact the end of the hub.
- Remove the hub and install the keys in the shaft.
- Heat the hub (177 °C) in an oven until the bore is sufficiently larger than the shaft. Do not exceed 260 °C.
- When the hub expanded, install it quickly on the shaft to the "zero" set point. Continue to advance the hub up the taper to the desired axial position.

5) Shaft Alignment

- Use an inside micrometer or a spacer bar equal in thickness and at 90° intervals to measure the distance between hubs to gap.
- The "Angular Misalignment" value is the maximum difference between the measurements X and Y taken at opposite ends of the flanges.

6) Sleeve Installation

- Insert gasket between flanges and gap disc into counter bore of each rigid hub for floating shaft assemblies, and bolt flanges together.
- Check the alignment of the coupling. Determine "W" by measuring distances "W"max and "W"min between flex hub and sleeve using a depth micrometer or feeler gauges. The difference between "W"max and "W"min must not exceed the "W" value.

Annual Maintenance

1. Check alignment. If the maximum operating misalignment values are exceeded, realign the coupling.
2. Inspect oil-ring and gasket to determine if replacement is required.
3. Re-lubricate coupling if using general purpose grease until an excess appears at an open hole.

Gear Couplings

Alignment Data

To improve the service life of the coupling, shafts should be aligned to minimize deflection of the flexing elements. Shaft alignment is required in the axial, parallel, and angular directions, with each of these values not to exceed the recommended installation limits. Shaft alignment can be measured using various established methods, including Laser Alignment, Reverse Dial Indicator, and Rim and Face.

Disc Flexible Couplings

KCP Disc Flexible Couplings are designed to obtain the best capacity to weight ratio. They can reliably be used for mechanical power transmission.

Disc Couplings are used in heavy duty, slow to medium speed applications where high starting torque, torque reversals, continuous alternating torques, and/or shock loads are present. Examples include centrifugal pumps, compressors, ventilators, generators, turbines, electric motors, paper machines, machine tools, cooling towers, and printing machines.

The simple form of the Disc Coupling enables quick installation. The center member, generally an open lug type, minimizes the space required for installation while providing sufficient clearance for assembly. The central member provides excellent dynamic balance, which improves the life of the couplings. Disc Couplings are virtually free from periodic maintenance and do not require lubrication. All components are made of SM45C.

The central member is self-centering and does not require limiting devices or axial float devices for the shaft. The units, including blades and fasteners, are supplied as a single set, which reduces the number of loose parts and makes installation and replacement simple.

Tire Couplings

KCP Tire Couplings provide an ideal flexible coupling and include features such as Taper Bush fixing. Tire Couplings create a torsionally elastic coupling and offer a choice of flange combinations to suit most applications. The flanges are available in either Face or hub Taper Bush fitting, or can be bored to size, increasing the versatility for designers and engineers. The couplings can accommodate a standard distance between shaft ends through the addition of a spacer flange. This simple addition can facilitate equipment maintenance.

Tire Couplings are comprised of symmetrical shapes. The symmetry ensures balance and safety while minimizing the existing imbalance in any assembly. Replacing the tire and rubber parts is quick and simple and can be performed without displacing the equipment. This significantly reduces machine downtime. Maintenance costs are also reduced compared to other assemblies because Tire Coupling components do not require lubrication.

The flexible tire provides excellent shock-absorbing properties which reduce vibration and torsional oscillation. By isolating vibrations between machines and motors, workplace noise emissions are considerably reduced, greatly improving the workplace environment. In addition to mechanical isolation, Tire Couplings ensure perfect electrical isolation between shafts, removing a important cause of bearing failure.

KW Flex Couplings

KCP KW Flex Coupling is designed to allow for quick and easy element replacement. Removal of hubs or the realignment of motors or drives is not required, which in turn reduces overall downtime.

Advanced production methods and innovative material selection allows for a higher capacity at a more competitive price.

KW Flex Coupling is non-lubricated and are designed from flexible urethane. The lack of need for lubrication decreases recurrent maintenance costs.

Available in both close-coupled and spacer designs, Urethane Flexible Couplings accommodate shaft diameters up to 186mm and torque loads up to 15,028 Nm

The urethane element has excellent resistance to wear and chemicals, and can be operated between temperatures of -40°C to 95°C .

The compact design of this coupling eliminates that need for coupling guard redesign for specific applications.

Max Dynamic & Field Couplings

The unique halved flex element and reversible hubs reduce inventory and assembly time.

Max Dynamic Couplings are non-lubricated, material-flexing couplings constructed of a specially formulated polyurethane material designed for maximum durability, strength and fatigue resistance.

The polyurethane material bonded to metal eliminates assembly and slippage problems that often occur with mechanically clamped designs.

Due to their simple structure, Max Dynamic Couplings can be easily replaced or maintained without the separation of motors or connectors on the related line. Some misalignment of components in certain system is unavoidable. This coupling provides high misalignment capacity and low reactionary forces due to misalignment. The torsionally soft flex element cushions shock loads and vibration, which in turn extends equipment life.

Nylon Coupling

KCP Nylon Coupling is torsionally rigid power transmission couplings. Their flexible shaft connections transmit torque between two steel gear hubs and the internal teeth of a nylon drive sleeve. These couplings are specifically suitable to compensate for shaft misalignment, whether axial, radial, and/or angular.

Single or double engagement options make the Nylon Couplings suitable for a variety of applications. The spacer type connections can accommodate large shaft end gaps. Nylon couplings can be assembled both vertically and horizontally. There is no need for any special assembly tools. Nylon Couplings are non-lubricated and low noise.

The steel hubs and nylon sleeves are a material combination that allows for maintenance-free, continuous operation and very low friction on the teeth. In the case of misalignment in couplings between hubs with spur teeth, high edge pressure can develop on the contact surfaces. This can lead to considerable wear.

The curved teeth of the Nylon Couplings avoid edge pressure on the coupling, even in the case of angular and radial misalignment.

Wire Drum Coupling

KCP Wire Drum Coupling is designed for installation in the drum drive of crane or conveying systems. This coupling can be used in the difficult and rough operating conditions associated with iron and steel work, or in the continuous heavy load operations of shore cranes.

Wire Drum Coupling absorbs pressure stress caused by the high torque and high radial loads resulting from the larger surface areas of these applications.

The design of this coupling prevents the danger of roller and bore breakage due to bending stress. The circular teeth on this coupling produces dramatically lower stress as compared to the bending stress involved with typical gear teeth.

The torque moment in the coupling is transmitted in two ways. First, through the two drag faces of the sleeve which is housed in the drum. Secondly, through a series of bolts which are fixed to the drum.

Wire Drum Coupling can compensate for angular misalignments of up to 1° , via a crown which allows the hub to oscillate with respect to the sleeve.

Depending on the size of the selected coupling, axial displacements from $\pm 3\text{mm}$ up to $\pm 8\text{mm}$ can be absorbed. Such couplings are not suitable for absorption or transmission of axial forces.

The following figure shows an example assembly of a Wire Drum Coupling in a hoisting gear. The coupling's hub is placed at the end of the wire drum. The bearing bracket must be configured as a fixed bracket.

Flange Flexible Couplings

KCP Flange Flexible Couplings are used to connect shaft lines.

Flange Couplings transmit power smoothly, and these couplings can absorb shock load and vibration.

Flange Couplings do not require lubrication and are virtually maintenance free. The simplified form of this piece enables a quick and easy installation. These couplings are easy and low cost to assemble and disassemble.

The Flange Flexible Couplings can safely operate without any hard covers.

Universal Joints

KCP Universal Joints are considered to be one of the oldest flexible couplings.

The Universal Joints, in their simplest form, consist of two shaft yokes at right angles to each other and a four point cross which connects the yokes. The cross sits inside the bearing cap assemblies, which are pressed into the eyes of the yokes.

The modern Universal Joints have become much more complex than their simple ancestor described above. In general, industrial applications must operate continuously with high torque loads. Industrial applications demand maximum strength and life of all components, including Universal Joints.

Universal Joints have several unique features that make it ideal for a variety of application. The most significant of these features is the ability of the Universal Joints to operate at high misalignment angles.

Another key feature of Universal Joints is the design of the bearing and seal, which resists lubrication loss and contamination. This makes Universal Joints suitable for applications where harsh atmospheric conditions would prohibit the use of other couplings.

The Universal Joints can be used either as a single joint or in pairs. However, use of the Universal Joints as a single joint, only accommodates angular misalignment.

Since nearly every application requires the coupling to accommodate offset misalignment as well as angular, the Universal Joints should be used in pairs. Using the Universal Joint in pairs also corrects for any non-uniform angular velocity that can be caused by a single joint.
